## Register of HBsAg Positive Donations

A preliminary report was issued several years ago. It was intended that this would be followed by annual updates and extensions of the analysis as data became available and as time permitted. We are, as yet still working towards this ideal. The main reasons for delay are, paradoxically, at opposite ends of the spectrum: on the one hand, the huge amount of archived data received from some centres and on the other hand the delay in receiving figures from others. In future we will attempt to work to deadlines to produce a report by the end of February each year based on all data received by the end of the first week of January, regardless of omissions. Unfortunately such omissions will make comparative analyses complicated and will thereby reduce the overall value of the exercise. Obviously we are receptive to any suggestions that colleagues may have for resolving the difficulties.

The same basic format will be maintained each year so that individual RTCs can monitor their own statistics and compare them with any national trends. While maintaining the basic format we will try and introduce improvements in presentation and also extra analyses.

Table 1 is an example of the basic spreadsheet that has been devised. It contains the figures received from the RTCs and shows the initial calculations. Each centre will receive a copy of their own spreadsheet. Initially we have assumed that first time donors comprise one sixth of the total number of donors bled, unless it was specified otherwise. However, for later years we have taken 'new donor' totals from the anti-HIV returns. The other figures are calculated as follows (the letters refer to the column identification on the spreadsheet):

$$\begin{aligned}
 F &= (C/B) \times 100000, \\
 G &= (D/E) \times 100000, \\
 H &= B/C, \\
 I &= E/D, \\
 J &= (D/C) \times 100
 \end{aligned}$$

Thus F is the overall HBsAg rate expressed as the number of HBsAg positives per 100,000 donations and H is the same figure expressed as a rate i.e. 1:xxx. G and I are the comparable figures for first-time donors. J is the percentage of HBsAg positives who are first-time blood donors. We would expect all HBsAg positives from previously tested donors to be from donors infected since the time of their last donation and thus this figure should be close to 100%, with

a very small component from donors contracting HBV since their last donation; [nb we are aware of the possibility that donors may be bled as 'old donors' when their previous [first] donation has not been tested, perhaps because it was a 'part pack with no samples available for testing].

It is possible that some centres will not have detected any HBsAg positives in a year. This will appear in the tables as zero. Because of the statistical shortcomings of dealing with small denominators and large numerators we have summarised data by grouping the three Thames centres together, the five Scottish Centres and the other centres as the 'Rest of UK'. There is also a summary for the total UK.

Tables 2a, b and c compare the total HBsAg positive rate in the RTCs per 100,000 donations (from new and established donors) per year. The table also shows the values for 'Thames', Scotland, the Rest of the UK and the total for the UK. This summary is also presented graphically in Figure 2.

Tables 3a, b and c compare the HBsAg positive rate for first-time donors between centres and is presented in the same format as above. If the number of first-time donors bled has not been reported or available from the 'anti-HIV testing data' we have assumed it to be one sixth of the total donations. Figure 3 is a graphic representation of the 3 preceding tables.

Tables 4a, b and c show the percentage of HBsAg positives who are first-time donors. This is shown graphically in figure 4. We would expect this figure to be close to 100% with a very low rate of HBsAg positivity in established donors, and those found positive being recent infections. There are striking differences between centres in this respect, which merits further investigation.

Table/figure 5 shows the change with time of the ratio of HBeAg to anti-HBe for various groups of donors. There is no obvious change with time for the various groups. It appears that UK born donors have a higher ratio [i.e. there are more anti-HBe than HBeAg] than do donors born outside the UK.

Table/figure 6 shows the proportion of males to females and how it changes by year. We would expect the numbers of male HBsAg positive donors to have decreased with the introduction of self-exclusion by donors at risk of contracting AIDS. However no such change is obvious, possibly reflecting a preponderance of carriers from areas where HBV infection is endemic.

We regret the delay in production of this report but future updates of the computer files will now be much easier. The spreadsheets and databases are complex and there is always the possibility that an error may occur. We apologise if this is the case and would be very grateful for any feed-back. We have attempted to improve the appearance of the notification form and a blank is enclosed.
